

The story of the Vaiont landslide told through the photographs of Edoardo Semenza

The morning after the landslide of October 9, 1963 - 2

31 - Panorama of the landslide from Casso

D - The numbers on the landslide

Volume 270 Mm³

Area ~ 2 km²

Maximum thickness 330 m

Width of the landslide front 1,85 km

Horizontal displacement 350-380 m

Maximum displacement 450-500 m along the sliding surface

Estimated maximum velocity 20-30 m/sec

Victims 1910

When the landslide entered the reservoir, it generated a huge displacement wave, that from an elevation of 700 m rose up to 930 m on the opposite slope and divided into three parts: one part flowed to the east; another back down onto the landslide mass to the south; and a third to the west over and beyond the dam. At least 25 million m³ of water flowed over the dam, destroying most of Longarone. The wave striked groups of houses with their inhabitants in other villages, both in Vaiont and Piave Valleys.

Only the dam withstood the might of the

wave.

Seismograms at stations within the region registered the landslide and the impact of the wave on the Piave Valley: the rock mass begun fast sliding along Monte Toc slope at 10:39:46 p.m. and came to rest less than one minute later. The wave overtopped the dam at 10:40 p.m. and in approximately 12 minutes destroyed Longarone and other towns in the Piave Valley.

Most of the failed rock mass retained its structure, with little change in shape apart from a general rotation that is evident in the surface morphology. Multiple sliding surfaces were generated within the main mass along the less rigid levels of the formations involved in the movement.

Panoramic view from the village of Casso of the Eastern Rocky Slabs of the main scarp (LOr), the Internal Lake (B) and the slide mass. Behind the slide mass are the badlands of the Pineda landslide (P). On the left, the North (N) and Northwest (NW) walls of Punta del Toc, separated from the opposite side of the Vaiont Valley by a series of depressions. Colle Isolato (CI), the Northwest Valley (V) and Costa Rossa (CR) lie below the center of the photograph. Apart from its front, the surface of the slide mass has a gentle shape similar to a plateau. On this surface are the eastern and western Debris Blocks (ZD) and the Pozza Plateau (AP). Near the center of the photo, the steep slope delineates the Col Tramontin fault, which is the East Boundary of the landslide (MO). Between it and the Pozza Plateau, the East Lobe of the slide mass (LO) is also visible; it retained, for the most part, its original vegetation cover.

One can distinguish almost all the details of the landslide in this panoramic photo. At the lower right are three craters; two more appeared in the following days. At the top are the two parts of the failure surface. Downslope are the two most distal parts of the landslide mass – the two wooded Lobes, LW (western) and LE (eastern) that were not affected by the return flow of water from the displacement wave that completely removed the vegetation from the rest of the slide mass. At the center of the photo is Massalezza Lake (B), which formed at the junction of the eastern and western branches of the Massalezza Stream in the depression created by the back rotation of the slide mass. Water from the displacement wave filled this depression, and the lake persisted for a long time.

At the left, one can see part of the Pineda landslide (P) and the lake upstream of it. NW is the Northwest Wall of the Pian del Toc. ZO is a small mass that began to move with the rest of the slide but then was pushed westward by the principal slide mass and came to rest almost immediately. To the right and below the symbol ZO is the south slope of the valley at the side of the dam, which is composed of east-dipping strata of Vaiont Limestone. Toward the lower left, one can see the alluvial fan (CNW) that formed immediately after the landslide by the part of the wave that flowed out of the valley along the frontal part of the landslide. Just uphill, this water also cut a small channel that is clearly visible on the light-coloured plain underlain by sediment deposited by the last phase of the wave as it sped toward the dam. To the left of this plain is Colle Isolato (CI).

The village was not directly hit by the wave, but it was damaged by forceful sprays of water and by rocks that were pushed out in front of the wave. Some rocks broke through the roofs of several houses. The most serious damage was done to the house in the foreground and to the school at the lower right.
